# Module3

June 1, 2022

### 0.0.1 Grading

The final score that you will receive for your programming assignment is generated in relation to the total points set in your programming assignment item—not the total point value in the nbgrader notebook. When calculating the final score shown to learners, the programming assignment takes the percentage of earned points vs. the total points provided by nbgrader and returns a score matching the equivalent percentage of the point value for the programming assignment. **DO NOT CHANGE VARIABLE OR METHOD SIGNATURES** The autograder will not work properly if your change the variable or method signatures.

#### 0.0.2 Validate Button

Please note that this assignment uses nbgrader to facilitate grading. You will see a validate button at the top of your Jupyter notebook. If you hit this button, it will run tests cases for the lab that aren't hidden. It is good to use the validate button before submitting the lab. Do know that the labs in the course contain hidden test cases. The validate button will not let you know whether these test cases pass. After submitting your lab, you can see more information about these hidden test cases in the Grader Output. Cells with longer execution times will cause the validate button to time out and freeze. Please know that if you run into Validate time-outs, it will not affect the final submission grading.

# 1 Module 3: Logistic Regression

```
from math import exp
import numpy as np
import pandas as pd
from sklearn.linear_model import LogisticRegression
from sklearn.datasets import load_breast_cancer
from sklearn.model_selection import train_test_split
import matplotlib.pyplot as plt
%matplotlib inline

from sklearn.metrics import roc_auc_score
from sklearn.metrics import roc_curve
```

### 1.0.1 Binary classification with logistic regression.

Part A [5 points]: Your first task is to complete the function gen\_logistic in the following cell so as to be able to generate the logistic function for a given input. The logistic function is a type of sigmoid function which has an 'S'-shape and 'squashes' its inputs to a value lying in the range [0,1]. Other sigmoid functions include the hyperbolic-tangent function (tanh(x)) and the error function (erf(x)).[https://en.wikipedia.org/wiki/Sigmoid\_function]

```
[298]: def sigmoid(z):
           return 1 / (1 + \exp(-z))
[299]: def gen_logistic(x, w=1, b=0):
           outputing the logistic output for an input x
           :param x: scalar or numpy array of shape (n_samples, n_features). If only \Box
        \rightarrow one feature, it must have the shape of (n_samples,1).
           :param w: weight(s); either scalar or numpy array of shape (1, n_features)
           :param b: bias; either scalar or numpy array of shape (1,)
           returns y of shape (n_samples,)
           # TODO: Finish this function to return the output of applying the sigmoid
           # function to the input x (Please do not use external libraries) store
           # the output in y and return y. Do not change the default parameter values.
           # Hint: This function will be used in any input shape scalar (Od), 1du
        \rightarrowvector, and 2d arrays. Please make sure it can handle all those. Following
        →reshaping codes might help.
           # Hint2: You may use design matrix using concatenation, but it is not,
        \rightarrownecesary.
           \Lambda = 0
           if np.isscalar(x):
             x = np.array(x).reshape((1,1))
```

```
if np.isscalar(w):
      w = np.array(w).reshape((1,1))
    if np.isscalar(b):
      b = np.array(b).reshape((1,1))
   if b.shape==(1,):
      b= b.reshape((1,1))
    # your code here
   y = np.empty(x.shape[0])
   if w.shape == (1,1):
        for i in range(0, len(x)):
            z = w * x[i] + b
            y[i] = sigmoid(z)
        return np.array(y)
   else:
        for i in range(0, len(x)):
            z = np.dot(w, x[i]) + b
            y[i] = sigmoid(z)
        return np.array(y)
# .reshape(y)
# .shape[0],
```

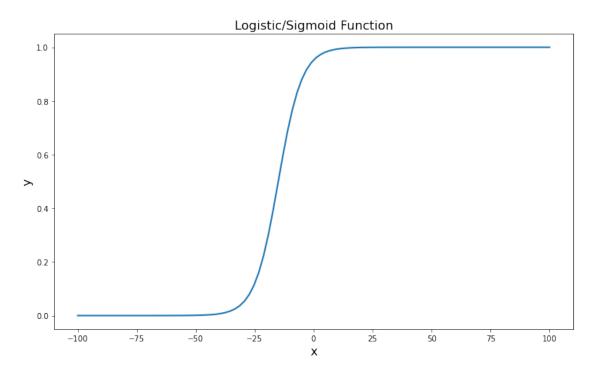

```
[300]: # tests that gen_logistic function returns the output of applying the sigmoid_ \rightarrow function to the input x # ouput is stored and returned in y
```

Part B [5 points, Peer Review]: Generate a vector x of length N with values lying between limits Xa and Xb (for this you will have to choose your own limits; play around with different values) and apply the gen\_logistic function to this vector. Proceed to plot the output and verify the shape of the output. If your decision boundary value is about the center of your x range, you will see an S-shape. Complete the Peer Review section for this section.

```
x = np.expand_dims(np.linspace(Xa,Xb,N), axis=1)
y = gen_logistic(x, w, b)

fig, ax = plt.subplots(nrows=1,ncols=1,figsize=(12,7))
ax.plot(x,y, lw=2)
ax.set_xlabel("x", fontsize=16)
ax.set_ylabel("y", fontsize=16)
ax.set_title("Logistic/Sigmoid Function", fontsize=16)
```

[301]: Text(0.5, 1.0, 'Logistic/Sigmoid Function')

1. Increasing w will make the curve transition sharply: [2 pts, True/False]

```
[302]: # uncomment sharp_transition and answer qustion 1. above
# replace string with 'True' or 'False'
# your code here
sharp_transition = 'True'
[303]: # this cell tests sharp transition
```

2. If b increases by 1, then the decision boundary x decreases by 1: [3 pts, True/False]

```
[304]: # uncomment x_decreases_by_1 and answer question 2. above
# replace string with 'True' or 'False'
# your code here

x_decreases_by_1 = 'False'
```

[305]: # this cell tests x\_decreases\_by\_1

PART C [10 pts, Peer Review]: Performing binary classification using logistic regression on the breast-cancer dataset. In this part you will be exposed to different methods within the scikit-learn LogisticRegression class so you can build a classifier.

Import breast cancer dataset from sklearn [5 pts]

```
[306]: # Importing the breast-cancer dataset from sklearn datasets
       class BC data:
           11 11 11
           class to import the breast cancer dataset from sklearn
           11 11 11
           def __init__(self):
               x, y = load_breast_cancer(return_X_y= True)
               self.x_train = None
               self.x_test = None
               self.y_train = None
               self.y_test = None
               #TODO: Split the data into training and test data (use train_test_split_
        \rightarrowsklearn)
               # such that the test data size is 25% of total number of observations
               # No need to rescale the data. Use the data as is.
               # your code here
               self.x_train, self.x_test, self.y_train, self.y_test =_
        →train_test_split(x, y,
                        test_size=0.25, random_state=1214)
       data = BC_data()
```

```
[307]: data.y_train
[307]: array([1, 1, 1, 1, 0, 1, 0, 1, 0, 1, 0, 0, 0, 0, 1, 1, 1, 1, 1, 0, 1, 0,

1, 0, 1, 0, 0, 0, 0, 0])
```

[308]: # tests that you properly split data into training and test data # such that test dat size is 25% of the total number of observations

### Build and Fit Logistic Regression Model [5 pts]

```
[309]: # TODO: Use the data object and then train the logistic regression model.
# 1. Change the code below to build your model called LogReg
# 2. Fit the model to the train data

LogReg = None

# your code here
LogReg = LogisticRegression(class_weight="balanced", solver="liblinear").fit(
    data.x_train, data.y_train.ravel())
```

```
[310]: # weights
LogReg.coef_
```

```
[311]: # tests LogReg model
```

In the next cell, compute the ROC curve and the area under the curve and plot the ROC curve. Upload a copy or screenshot of the plot for this week's **Peer Review assignment**.

```
[312]: # TODO: compute the area under the curve and plot ROC curve

# Plot the ROC curve ( True positive rate v/s False positive rate) and indicate

the AUC on the plot

# your code here

y_prob = LogReg.predict_proba(data.x_test)

fpr, tpr, th = roc_curve(data.y_test, y_prob[:, 1])

auc = roc_auc_score(data.y_test, y_prob[:, 1])

plt.plot(fpr, tpr, 'k-')

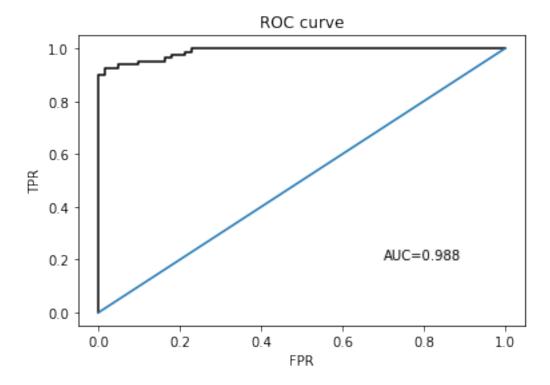

plt.plot(np.arange(0, 1.1, 0.1), np.arange(0, 1.1, 0.1))

plt.title('ROC curve')

plt.xlabel('FPR')

plt.ylabel('TPR')

plt.text(0.7, 0.2, 'AUC=' + "{:.3f}".format(auc));
```

Part D [5 pts, Peer Review]: Here we will use the trained model coefficients and generate the classification probabilities using the gen\_logistic function we built. The goal of this section is to make you understand how logistic regression classifies data points during and after training. Using the predictions from the generated probabilities, you will compute the precision and recall metrics (defined below).

```
[313]: def calculate_precision(y_true, y_pred, pos_label_value=1.0):
           This function accepts the labels and the predictions, then
           calculates precision for a binary classifier.
           Args
               y_true: np.ndarray
               y_pred: np.ndarray
               pos_label_value: (float) the number which represents the postiive
               label in the y true and y pred arrays. Other numbers will be taken
               to be the non-positive class for the binary classifier.
           Returns precision as a floating point number between 0.0 and 1.0
           111
           # your code here
           tp = 0
           fp = 0
           for i in range(0, len(y_true)):
               if y_pred[i] == pos_label_value:
                   if y_true[i] == y_pred[i]:
                       tp += 1
                   else:
                       fp +=1
           precision = tp / (tp + fp)
           return precision
       def calculate_recall(y_true, y_pred, pos_label_value=1.0):
           111
           This function accepts the labels and the predictions, then
           calculates recall for a binary classifier.
           Args
               y_true: np.ndarray
               y_pred: np.ndarray
               pos_label_value: (float) the number which represents the postiive
               label in the y_true and y_pred arrays. Other numbers will be taken
               to be the non-positive class for the binary classifier.
           Returns precision as a floating point number between 0.0 and 1.0
           111
```

```
# your code here
tp = 0
fn = 0
for i in range(0, len(y_true)):
    if y_pred[i] == pos_label_value:
        if y_true[i] == pos_label_value:
            tp += 1
    else:
        if y_true[i] == pos_label_value:
            fn +=1
recall = tp / (tp + fn)
```

```
[314]: # testing cell
# Sanity check tests
ut_true = np.array([1.0, 1.0, 0.0, 0.0])
ut_pred = np.array([1.0, 1.0, 1.0, 1.0])
prec = calculate_precision(ut_true, ut_pred, 1.0)
recall = calculate_recall(ut_true, ut_pred, 1.0)
```

In the next cell you will generate the predictions for the test data data.x\_test and compute prediction and recall metrics by calling the functions you built above. Take a screenshot of your code to submit for your Peer Review assignment. Make sure that you use the gen\_logistic function.

```
print('Model Precision : %0.2f' % precision)
print('Model Recall : %0.2f' % recall)
```

Model Precision : 0.93 Model Recall : 0.94
